

Virtual Seminar on Climate Economics

Federal Reserve Bank of San Francisco

Organizing Committee:

Glenn Rudebusch (Federal Reserve Bank of San Francisco)

Michael Bauer (University of Hamburg)

Stephie Fried (Arizona State University)

Òscar Jordà (Federal Reserve Bank of San Francisco)

Toan Phan (Federal Reserve Bank of Richmond)

The Fiscal Costs of Climate Change in the United States

Lint Barrage
FRBSF Virtual Seminar on Climate Economics

U.C. Santa Barbara & NBER

September 24, 2020

Introduction

- ▶ Climate change's fiscal impacts and policy implications
 - i. Existing programs (e.g., healthcare, wildfire suppression)
 - ii. Public adaptation (e.g., coastal infrastructure)
 - iii. Revenue impacts (e.g., employment, output effects)

Growing policy concern (e.g., U.S. GAO "High Risk" List)

- ▶ Benchmark Integrated Assessment Models (IAMs, e.g. DICE, Nordhaus, 1992, 2017; FUND, Anthoff and Tol, 2014; Golosov et al., 2014, etc.) typically do not consider/distinguish fiscal costs as such
- ▶ However, if gov't raises revenues with *distortionary* taxes:
 - ▶ Socially costly to raise, divert public funds
 - ▶ Fiscal constraints may limit adaptation, increase damages
 - ▶ Show: Change structure of optimal carbon price

This Paper

- ▶ Formalizes, aggregates, quantifies fiscal cost effects in IAM
1. Set up macro climate-economy model with fiscal impacts
 - ⇒ Theoretical optimal policy implications
 2. Bottom-up quantification of fiscal impacts
 - ⇒ Prior literature, data, forecasts
 3. Quantitative U.S. fiscal policy climate-economy model
 - ⇒ Welfare, fiscal implications of carbon pricing

Literature

- ▶ Climate-economy models, IAMs (Nordhaus, 1992, 2017; Manne, Richels, 2005; Anthoff, Tol, 2014; Golosov et al., 2014; vd Ploeg, Withagen, 2014; etc.), **Adaptation** (e.g., Hope, 2006; Tol, 2007; deBruin et al. 2009; Bosello et al., 2010; Agrawala et al. 2010; Belfiori 2015; Fried 2019)
 - ▶ Distortionary taxes: Barrage (2020)
 - ▶ Here: +Fiscal climate impacts, U.S. model
- ▶ Pollution mitigation and fiscal policy (Sandmo 1975, Bovenberg, de Mooij 1994; Goulder 1995; Bovenberg Goulder, 1996; Williams 2002, Babiker et al. 2003; Goulder et al. 2014; Fried et al. 2018; etc.)
 - ▶ Here: Integrated assessment, output & public spending impacts
- ▶ Fiscal impacts of weather events (Noy, Nualsri, 2011; Deryugina, 2017), climate change (e.g., IMF, 2008; CBO, 2016; OMB, 2016)
 - ▶ Here: Integrate into IAM, analyze implications

Talk Outline

1. Introduction
2. Model
 - ▶ **Setup**
 - ▶ Qualitative Results
3. Quantification
 - ▶ Existing Public Program Costs
 - ▶ Sea Level Rise Adaptation
 - ▶ Rest
4. Numerical Results
5. Conclusion

Households

- ▶ Infinitely-lived, rep. household with well-behaved **preferences** over consumption C_t , labor L_t , climate change T_t :

$$U_0 \equiv \sum_{t=0}^{\infty} \beta^t U(C_t, L_t, T_t, \Lambda_t^u)$$

- ▶ where $\Lambda_t^u \in [0, 1) \sim$ adaptive capacity against climate utility impacts (e.g., damages to national parks)
- ▶ Further assume:

$$U(C_t, L_t, T_t, \Lambda_t^u) = v(C_t, L_t) + h[(1 - \Lambda_t^u) T_t]$$

Household Flow Budget Constraint

$$\begin{aligned} & C_t + \rho_t B_{t+1} + K_{t+1} \\ \leq & w_t(1 - \tau_{lt})L_t + \left\{ 1 + (r_t - \delta(SLR_t, \Lambda_t^{slr}))(1 - \tau_{kt}) \right\} K_t \\ & + B_t + \Pi_t + G_t^T(T_t) \end{aligned}$$

$B_{t+1} \sim$ bond purchases

$\rho_t \sim$ price of one-period bond

$K_{t+1} \sim$ private capital stock

$w_t \sim$ wage rate

$\tau_{lt} \sim$ labor income tax rate

$r_t \sim$ return on capital

$\tau_{kt} \sim$ capital income tax rate

$\delta(\cdot) \sim$ depreciation rate

$SLR_t \sim$ sea level rise

$\Lambda_t^{slr} \sim$ adaptive capacity

$\Pi_t \sim$ profits from energy sector

$G_t^T(T_t) \sim$ gov't transfers

Production

- ▶ **Final Good:** Production CRS in L_{1t} , K_{1t} and energy E_t

$$\begin{aligned} Y_t &= F_1(A_{1t}, L_{1t}, K_{1t}, E_t, T_t, \Lambda_t^y) \\ &= (1 - D(T_t)(1 - \Lambda_t^y)) \cdot A_t \tilde{F}_1(L_{1t}, K_{1t}, E_t) \end{aligned}$$

- ▶ $D(T_t)$ gross climate damages, Λ_t^y adaptive capacity

- ▶ **Energy Input:** CRS extraction technology:

$$E_t = F_2(A_{Et}, L_{2t}, K_{2t})$$

- ▶ Provide fraction μ_t from clean tech. at extra cost

Model Overview: Government

- ▶ **Expenditures:** Must raise revenues to finance

- ▶ Household transfers $G_t^T(T_t) \geq 0$

- ▶ Consumption: $G_t^C(T_t)$

- ▶ Initial debt B_0

- ▶ May choose to fund $(\lambda_t^y, \lambda_t^u, \lambda_t^{slr})$ adaptation:

$$\Lambda_t^i = f^i(\{\lambda_s^i\}_{s=0}^t) \text{ for } i \in \{u, y, slr\}$$

- ▶ **Revenues:**

- ▶ Linear taxes on labor income τ_{lt}

- ▶ Linear taxes on net-of-depreciation capital income τ_{kt}

- ▶ Excise taxes on energy inputs τ_{lt}

- ▶ Excise taxes on carbon emissions τ_{Et}

- ▶ One-period bonds

- ▶ **Marginal Cost of Public Funds (MCF_t):** Welfare cost of raising extra dollar of gov't revenue

- =1 in standard setting (lump-sum taxes)

- >1 with distortionary taxes

Climate

- ▶ **Temperature change** depends on U.S. carbon emissions E_t^M plus rest-of-world (ROW) emissions E_t^{ROW} :

$$T_t = F_t(E_0^M + E_0^{ROW}, E_1^M + E_1^{ROW}, \dots, E_t^M + E_t^{ROW})$$

- ▶ Benchmark: E_t^{ROW} exogenous, but also consider ROW response elasticity to U.S. mitigation

- ▶ **Sea level rise** depends on history of temperature change (Rahmsdorf, 2007):

$$SLR_t = G(SLR_0, T_1, T_2, \dots, T_t)$$

Climate Impacts and Policy: Summary

► Climate Change Impact Channels:

- [Standard]: Production: $Y_t = D(T_t) \cdot F(.)$
- Utility: $U(C_t, L_t, T_t)$
- Capital depreciation: $\delta(SLR_t, .)K_t$
- [New]: Government consumption: $G_t^C(T_t)$
- [New]: Government transfers: $G_t^T(T_t)$

► Government Policy Choices:

- [Standard]: Carbon tax τ_{Et}
- Capital, labor, taxes τ_{kt}, τ_{lt} ; bonds B_t^G , gov't spending G_t^C , G_t^T ...
- [New]: Public adaptation $\Lambda_t^y, \Lambda_t^u, \Lambda_t^{slr}$

Talk Outline

1. Introduction

Optimal Mitigation

Define:

$$M_{t,j} \equiv \begin{cases} 1 & \text{if } j = 0 \\ \beta^j \prod_{m=1}^j \frac{1}{(1+r_{t+m}-\delta_{t+m})} & \text{o.w.} \end{cases}$$

Optimal Mitigation

Result 1 *The optimal carbon tax in period $t > 0$ is implicitly defined by:*

$$\begin{aligned}\tau_{Et}^* = & \text{PV [Output Impacts]} \\ & + \left(\frac{1}{MCF_t} \right) \text{PV [Utility Impacts]} \\ & + \text{PV[Sea Level Rise Impacts]} \\ & + \text{PV[Gov't Consumption Impacts]} \\ & + \left(\frac{MCF_t - 1}{MCF_t} \right) \text{PV[Gov't Transfer \& Offer Curve Impacts]}\end{aligned}$$

Optimal Mitigation

Result 1 *The optimal carbon tax in period $t > 0$ is implicitly defined by:*

$$\begin{aligned}\tau_{Et}^* = & \sum_{j=0}^{\infty} M_{t,j} \cdot \frac{-\partial Y_{t+j}}{\partial T_{t+j}} \cdot \frac{\partial T_{t+j}}{\partial E_t^M} \\ & + \left(\frac{1}{MCF_t} \right) \text{PV [Utility Impacts]} \\ & + \text{PV[Sea Level Rise Impacts]} \\ & + \text{PV[Gov't Consumption Impacts]} \\ & + \left(\frac{MCF_t - 1}{MCF_t} \right) \text{PV[Gov't Transfer \& Offer Curve Impacts]}\end{aligned}$$

Optimal Mitigation

Result 1 *The optimal carbon tax in period $t > 0$ is implicitly defined by:*

$$\begin{aligned}\tau_{Et}^* = & \text{PV [Output Impacts]} \\ & + \left(\frac{1}{MCF_t} \right) \text{PV [Utility Impacts]} \\ & + \text{PV[Sea Level Rise Impacts]} \\ & + \text{PV[Gov't Consumption Impacts]} \\ & + \left(\frac{MCF_t - 1}{MCF_t} \right) \text{PV[Gov't Transfer \& Offer Curve Impacts]}\end{aligned}$$

Optimal Mitigation

Result 1 *The optimal carbon tax in period $t > 0$ is implicitly defined by:*

$$\begin{aligned}\tau_{Et}^* = & \text{PV [Output Impacts]} \\ & + \sum_{j=0}^{\infty} \beta^j \left(\frac{1}{MCF_t} \right) \left[\frac{-U_{T_{t+j}}}{U_{ct}} \right] \frac{\partial T_{t+j}}{\partial E_t^M} \\ & + \text{PV[Sea Level Rise Impacts]} \\ & + \text{PV[Gov't Consumption Impacts]} \\ & + \left(\frac{MCF_t - 1}{MCF_t} \right) \text{PV[Gov't Transfer \& Offer Curve Impacts]}\end{aligned}$$

*Bovenberg and van der Ploeg (1994), Bovenberg and Goulder (1996), ...

Optimal Mitigation

Result 1 *The optimal carbon tax in period $t > 0$ is implicitly defined by:*

$$\begin{aligned}\tau_{Et}^* = & \text{PV [Output Impacts]} \\ & + \left(\frac{1}{MCF_t} \right) \text{PV [Utility Impacts]} \\ & + \text{PV[Sea Level Rise Impacts]} \\ & + \text{PV[Gov't Consumption Impacts]} \\ & + \left(\frac{MCF_t - 1}{MCF_t} \right) \text{PV[Gov't Transfer \& Offer Curve Impacts]}\end{aligned}$$

Optimal Mitigation

Result 1 *The optimal carbon tax in period $t > 0$ is implicitly defined by:*

$$\begin{aligned}\tau_{Et}^* = & \text{PV} [\text{Output Impacts}] \\ & + \left(\frac{1}{MCF_t} \right) \text{PV} [\text{Utility Impacts}] \\ & + \sum_{j=0}^{\infty} \left[\sum_{m=0}^{\infty} M_{t,j+m} \cdot \frac{\partial \delta K_{t+m}}{\partial SLR_{t+m}} \frac{\partial SLR_{t+m}}{\partial T_{t+j}} \right] \frac{\partial T_{t+j}}{\partial E_t^M} \\ & + \text{PV} [\text{Gov't Consumption Impacts}] \\ & + \left(\frac{MCF_t - 1}{MCF_t} \right) \text{PV} [\text{Gov't Transfer \& Offer Curve Impacts}]\end{aligned}$$

Optimal Mitigation

Result 1 *The optimal carbon tax in period $t > 0$ is implicitly defined by:*

$$\begin{aligned}\tau_{Et}^* = & \text{PV [Output Impacts]} \\ & + \left(\frac{1}{MCF_t} \right) \text{PV [Utility Impacts]} \\ & + \text{PV[Sea Level Rise Impacts]} \\ & + \text{PV[Gov't Consumption Impacts]} \\ & + \left(\frac{MCF_t - 1}{MCF_t} \right) \text{PV[Gov't Transfer \& Offer Curve Impacts]}\end{aligned}$$

Optimal Mitigation

Result 1 *The optimal carbon tax in period $t > 0$ is implicitly defined by:*

$$\begin{aligned}\tau_{Et}^* &= \text{PV} [\text{Output Impacts}] \\ &+ \left(\frac{1}{MCF_t} \right) \text{PV} [\text{Utility Impacts}] \\ &+ \text{PV} [\text{Sea Level Rise Impacts}] \\ &+ \sum_{j=0}^{\infty} M_{t,j} \cdot \frac{\partial G_{t+j}^C}{\partial T_{t+j}} \cdot \frac{\partial T_{t+j}}{\partial E_t^M} \\ &+ \left(\frac{MCF_t - 1}{MCF_t} \right) \text{PV} [\text{Gov't Transfer \& Offer Curve Impacts}]\end{aligned}$$

Optimal Mitigation

Result 1 *The optimal carbon tax in period $t > 0$ is implicitly defined by:*

$$\begin{aligned}\tau_{Et}^* = & \text{PV [Output Impacts]} \\ & + \left(\frac{1}{MCF_t} \right) \text{PV [Utility Impacts]} \\ & + \text{PV[Sea Level Rise Impacts]} \\ & + \text{PV[Gov't Consumption Impacts]} \\ & + \left(\frac{MCF_t - 1}{MCF_t} \right) \text{PV[Gov't Transfer \& Offer Curve Impacts]}\end{aligned}$$

Optimal Mitigation

Result 1 *The optimal carbon tax in period $t > 0$ is implicitly defined by:*

$$\begin{aligned}\tau_{Et}^* &= \text{PV [Output Impacts]} \\ &+ \left(\frac{1}{MCF_t} \right) \text{PV [Utility Impacts]} \\ &+ \text{PV[Sea Level Rise Impacts]} \\ &+ \text{PV[Gov't Consumption Impacts]} \\ &+ \sum_{j=0}^{\infty} \beta^j \left(\frac{MCF_t - 1}{MCF_t} \right) \left[\frac{\partial G_{t+j}^T}{\partial T_{t+j}} \right] \left(\frac{U_{ct+j}}{U_{cct} C_t + U_{ct} + U_{lct} L_t - U_{cct} G_t^T(T_t)} \right) \frac{\partial T_{t+j}}{\partial E_t^M}\end{aligned}$$

Optimal Mitigation

Result 1 *The optimal carbon tax in period $t > 0$ is implicitly defined by:*

$$\begin{aligned}\tau_{Et}^* = & \text{PV [Output Impacts]} \\ & + \left(\frac{1}{MCF_t} \right) \text{PV [Utility Impacts]} \\ & + \text{PV[Sea Level Rise Impacts]} \\ & + \text{PV[Gov't Consumption Impacts]} \\ & + \left(\frac{MCF_t - 1}{MCF_t} \right) \text{PV[Gov't Transfer \& Offer Curve Impacts]}\end{aligned}$$

Optimal Adaptation

Result 2 *Public adaptation to reduce direct utility losses should be less-than-fully provided (distorted) if governments raise revenues with distortionary taxes. Public adaptation to reduce climate impacts on final goods production and sea level rise capital losses should be undistorted (fully provided) regardless of the welfare costs of raising revenues.*

- ▶ Intuition: Productivity benefits compensate for fiscal costs
- ▶ Optimal tax system maintains production efficiency (Diamond, Mirrlees, 1971); Provides public production inputs fully (Judd, 1999)

Talk Outline

1. Introduction
2. Model

 - ▶ Sea Level Rise Adaptation
 - ▶ Rest
4. Numerical Results
5. Conclusion

Public Program Costs: Overview

- ▶ Synthesize prior estimates:
 - ▶ Crop insurance subsidies: U.S. Dept. of Agriculture (2016)
 - ▶ Wildfire suppression: U.S. Forest Service (2015), OMB (2016)
 - ▶ Hurricane-related public disaster spending: CBO (2016)
 - ▶ Air quality, health: Garcia-Menendez et al. (2015), OMB (2016)
 - ▶ West Nile Neuroinvasive Disease: EPA (2017)
 - ▶ Urban drainage infrastructure: EPA (2017)
- ▶ Own estimates: Wildfires and public healthcare
- ▶ Hybrid: Hurricanes and public healthcare, transfers; Deryugina (2017); Emmanuel et al. (2008); Bakkensen and Barrage (2019)

1) Synthesizing Prior Estimates:

Federal Crop Insurance Program Cost Increase by 2080

	RCP 8.5	RCP 4.5	Source
Increase	+40%	+23%	USDA (2016), OMB (2016)
Global Temp. Change (by 2075)	2.85 C	1.6 C	IPCC (2014)
Per 1 C impact:	+14.0%	+14.4%	

Wildfire Suppression Cost Increases

	RCP 8.5		Source
	2041-59	2081-99	
Global Temp. Change	2.0 C	3.7 C	IPCC (2014)
Forest Service	+117%	+192%	OMB (2016), USDA FS (2015)
Per 1 C impact:	+58.5%	+51.9%	
Dept. of Interior	+45%	+72%	OMB (2016), USDA FS (2015)
Per 1C impact:	+22.5%	+19.5%	

1) Synthesizing Prior Estimates:

Hurricane Relief Spending Increase by 2075

	RCP 8.5	Source
Increase due to climate change	+14%	CBO (2016)
Global Temp. Change (by 2075)	2.85C	IPCC (2014)
Per 1C impact:	+5%	
*Includes FEMA aid, HUD, Army Corps of Engineers, DOD, DOT		

Urban Drainage Infrastructure Costs (50-yr Storm)

	RCP 8.5		RCP 4.5		Source
	2050	2090	2050	2090	
Global Temp. Change	2.0C	3.7C	1.4C	1.8C	IPCC (2014)
Annual Cost (\$2015 bil)	4.3	5.6	3.7	4.1	EPA (2017)
Per 1C impact:	2.2	1.5	2.6	2.3	
Regression coefficient per 1C					+\$1.83 bil./yr

1) Synthesizing Prior Estimates:

Ambient Air Quality

		Source
2100		
Global Temp. Change	6.0 C vs. 1.5C	Garcia-Menendez et al. (2015), OMB (2016)
Federal healthcare	+1.2 bil./yr	Garcia-Menendez et al. (2015), OMB (2016)
Per 1 C impact:	+267 \$mil./yr	

West Nile Neuroinvasive Disease

	RCP 8.5		RCP 4.5		Source
	2050	2090	2050	2090	
Global Temp. Change	2.0C	3.7C	1.4C	1.8C	IPCC (2014)
Additional Cases	720	2200	510	800	EPA (2017)
→ Federal costs (\$ mil./yr)	\$14.5	\$45.1	\$10.5	\$16.4	EPA (2017), CMS (2020)
Regression coefficient per 1C:	+\$10.5 mil/yr				

2) Own Estimates: Wildfires and Public Healthcare

- ▶ Wildfires have been linked to poor air quality, increased healthcare utilization (e.g., Ahman et al. (2012) on 2012 Colorado fires; Gan et al. (2017) on Washington 2012 fires; Fan et al. (2018) national model)
 - ▶ Miller, Molitor, Zou et al. (2019): National data
- ▶ Data: County-year panel (1996-2018)
 - ▶ Top quartile of wildfire states (National Interagency Fire Center)
- ▶ Public medical transfers: BEA "Regional Economic Accounts" (REA); Centers for Medicare & Medicaid Services (CMMS)
- ▶ Wildfire and smoke events; other weather events: NOAA
- ▶ Air quality ratings: Environmental Protection Agency
- ▶ Demographics: REA, National Center for Health Statistics

Income support - Hurricanes	varies by county	+0.11%

Talk Outline

1. Introduction
2. Model
 - ▶ Setup
 - ▶ Theory Results
3. Quantification
 - ▶ Existing Public Program Costs
 - ▶ **Sea Level Rise Adaptation**
 - ▶ Rest
4. Numerical Results
5. Conclusion

Sea Level Rise: Impacts and Adaptation

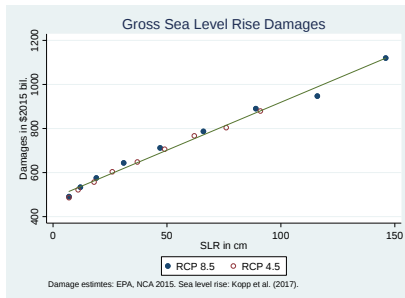

- ▶ Quantify based on EPA Coastal Property Model (Neumann et al., 2014a,b) runs for 2018 National Climate Assessment (EPA, 2017)
- ▶ Damages: Storm surge impacts, abandoned property costs
- ▶ Adaptation: Shoreline armoring, beach nourishment, elevation

Sea Level Rise: Impacts and Adaptation

- ▶ Quantify based on EPA Coastal Property Model (Neumann et al., 2014a,b) runs for 2018 National Climate Assessment (EPA, 2017)
- ▶ Damages: Storm surge impacts, abandoned property costs
- ▶ Adaptation: Shoreline armoring, beach nourishment, elevation

$$\delta(SLR_t, \Lambda_t^{slr}) = \bar{\delta} + (1 - \Lambda_t^{slr})f(SLR_t)$$

- ▶ Set $f(SLR_t) = \delta^{SLR} K_t SLR_t$ based on 'no adaptation' scen.

Sea Level Rise: Impacts and Adaptation

- ▶ Adaptation capital AK_t and effectiveness Λ_t^{slr} :

$$\Lambda_t^{SLR} = \left(\gamma_1 \frac{AK_t}{(\delta^{SLR} K_t^{SLR})} \right)^{\gamma_2} \quad (1)$$

$$AK_t \equiv \sum_{s=0}^{t-1} (\lambda_s^{slr} (1 - d^{slr})^s) + \lambda_s^{slr} \quad (2)$$

- ▶ Use EPA model output as 'observations'
- ▶ Select d^{slr} , γ_1 , γ_2 to minimize sum of squared errors between:
 - ▶ (1) and agg. damages with vs. without adaptation
 - ▶ Adaptation optimality condition $\frac{\partial \Lambda_t^{slr}}{\partial \lambda_t^{slr}} = \frac{1}{\delta^{SLR} K_t^{SLR}}$

$\Rightarrow d^{slr} = 0.246$ (annual depr. 2.8%), $\gamma_1 = 10.18$, $\gamma_2 = 0.09$

COMET-US Calibration: Fiscal Baseline

Avg. Effective Tax Rate	Rate	Source
Capital (τ_{k0})	29.0%	CBO (2014)
Labor	30.9%	OECD (2018)
Consumption	6.1%	Carey and Tchilinguirian (2000)
→ Labor-Cons. Wedge (τ_{l0})	35.1%	

- ▶ Base $\overline{G_0^T}$, $\overline{G_0^C}$: U.S. National Income and Product Accounts
 - ▶ Grow at rates of population, technology growth
 - ▶ Plus climate impacts: $G_t^j(T_t) = \overline{G_t^j}(1 + \alpha_{j,1}(T_t))$, $j=T,C$
- ▶ Initial debt: 2015 federal debt held by domestic public (FRED)
 - ▶ Extension in progress: COVID update

COMET-US Calibration: Other Climate Impacts

- ▶ Structurally, output impacts as in RICE/DICE model family:

$$(1 - D(T_t)) = \frac{1}{1 + \alpha_y T_t^2}$$

- ▶ Quantitatively, disaggregate RICE U.S. damages (0.90% at 2.5C):

Production	Utility
70%	30%

- ▶ Disaggregation procedure as in Barrage (2020a)
- ▶ Also subtract SLR impacts to avoid double-counting

Details

COMET-US Calibration: Other

- ▶ Match base year (2015) output (BEA), labor supply (OECD), carbon energy (EPA)
- ▶ Population, productivity growth: RICE Model (Nordhaus, 2011)
- ▶ Abatement costs $\Theta(\cdot)$: Match RICE per-ton costs (Nordhaus, 2011; Barrage, 2020)
- ▶ Carbon cycle, climate system: DICE (2010, 2016)
 - ▶ In progress: Update based on Dietz et al. (2020) (!)
- ▶ Preferences: CRRA, $\beta = (.985)^{10}$, $\sigma = 1.5$, Frisch labor supply elasticity 1.83 (Chetty et al., 2011)

Talk Outline

5. Conclusion

Fiscal Scenarios

► Income Taxes:

1. "First-Best": Gov't can levy non-distortionary lump-sum taxes
2. "Optimized Distortionary": Gov't can optimize (non-lump sum)
3. "Vary τ_l , BAU $\overline{\tau_k}$ ": Capital income taxes fixed at baseline ($\overline{\tau_k} = 29\%$), gov't can raise labor income taxes
4. "BAU $\overline{\tau_l}$, Vary τ_k ": Labor income taxes fixed at baseline ($\overline{\tau_l} = 35.1\%$), gov't can raise capital income taxes

► Carbon & Energy Taxes:

1. "No": Business-as-usual, no carbon/energy taxes until 2115
2. Otherwise: Optimized

Fiscal Costs Effects on Optimal Carbon Tax

Talk Outline

1. Introduction
2. Model
 - ▶ Setup
 - ▶ Theory Results
3. Quantification
 - ▶ Existing Public Program Costs
 - ▶ Sea Level Rise Adaptation
 - ▶ Rest
4. Numerical Results
5. **Conclusion**

Conclusion

- ▶ Consideration of fiscal setting and climate impacts:
- ▶ Changes optimal carbon price to account for:
 - ▶ Gov't consumption impacts (+20% per percent $\Delta G_t^C / ^\circ C$)
 - ▶ Gov't transfer impacts (+10% per percent $\Delta G_t^T / ^\circ C$)
- ▶ Changes adaptation spending optimality for utility damages
- ▶ Increases domestic welfare gains from carbon pricing
 - ▶ +10-400% with distortionary vs. lump-sum taxes
- ▶ Many caveats! But results highlight *potential importance* of fiscal effects $\Rightarrow$ Warrant further empirical, IAM consideration

Main Results: ROW Optimal

ROW Emissions: Global Optimum (RICE)

Back

COMET-US Calibration: Preferences

- ▶ Dynastic household lifetime utility:

$$\sum_{t=0}^{\infty} \beta^t N_t U(c_t, l_t, T_t)$$

$$U(c_t, l_t, T_t) = \frac{[c_t \cdot (1 - \zeta l_t)^\gamma]^{1-\sigma}}{1-\sigma} + \frac{(1 + \alpha_u T_t^2)^{-(1-\sigma)}}{1-\sigma}$$

- ▶ With $\beta = (.985)^{10}$, $\sigma = 1.5$
- ▶ ζ , γ set to match (i) base year labor supply (OECD), (ii) Frisch elasticity of labor supply 1.83 (Chetty et al., 2011)
- ▶ α_u set to match willingness-to-pay to avoid 2.5°C equal to 0.26 pct. of output in 2065

2) Wildfires and Public Healthcare: Specification

$$\ln Y_{j,t} = \gamma_j + \delta_t + (\theta_s \cdot t) + \beta_1 \ln \text{Fire/SmokeDays}_{j,t} + \mathbf{X}_{j,t}'\boldsymbol{\beta} + \epsilon_{j,t}$$

- ▶ $\ln Y_{j,t} \sim \ln$ p.c. public medical spending, $\gamma_j \sim$ county fixed effects, $\delta_t \sim$ year fixed effects, $(\theta_s \cdot t) \sim$ state-specific trend
- ▶ $\ln \text{FireDays}_{j,t} \sim$ num. fire or smoke days in county-year
- ▶ $\mathbf{X}_{j,t} \sim \ln$ of pop., pop > 65, inc. p.c.; pop. growth, inc. growth, pct. non-hisp. white; other weather days
 - ▶ "Medicare Controls": Medicare beneficiaries: ln. num, pct. female, pct. non-hisp. white, pct. Medicare Advantage, avg. age; county avg. Hierarchical Condition Category score
- ▶ Alternative: 2SLS isolating link from FireDays to number of days with "unhealthy" air (EPA) in county-year
